

A Resolution-Space Framework for Research Across Determinative and Non-Determinative Domains

Abstract. This document presents a research-space framework for investigating resolution across both determinative and non-determinative (ND/spiritual) domains. The framework is built on a set-theoretic foundation — Set Calculus — that treats temporal resolution as relational rather than strictly sequential. It defines a resolution space spanning from positive infinity, through a Klein transition interface, to negative infinity, and back, across n dimensions. The framework is presented as a valid research space rather than an accuracy claim: a structured domain within which research may validate, invalidate, or produce new answers, remaining deliberately decoupled from any single falsifiable hypothesis. Its status is explicitly preliminary — a defined but not fully characterized space. Provenance is preserved throughout; the framework derives from the Monadic Resolution Model as set out in the V8 (Resolve Through Monads) and V9 (Consolidated Monadic Resolution Model, including the RED Unified Set Laws) formalizations.

1. Framing

The present work is a research space, not a finished theory, and to call it merely “non-academic” would undersell it. It is a structured domain in which research could validate, invalidate, or find new answers to questions we may not even have thought to ask. The operational criterion for participation — “worked” — is that a human puts effort into the space and either finds a resolution space not previously explored, re-explores a space and reveals something new, or confirms or contradicts the findings of others. This criterion is deliberately non-gatekeeping: it does not require academic rigor as a precondition for entry, and it does not require the disambiguation of elements that cannot be separated. A closed boundary may be reopened when its governing rules permit; research may reopen boundaries rather than being permanently barred by them.

2. Theoretical Foundation: The Set Calculus Engine

The framework rests on a set-theoretic engine — the Monadic Resolution Model (V8 Resolve Through Monads; V9 consolidated model, including the RED Unified Set Laws) — that resolves, validates backward, reduces at sufficient relational closure, traces, and recurses. Within this engine:

- **Determinative dimension** (Sine/Prime): the resolved, persistent, determinative state.
- **Non-determinative/spiritual dimension** (Cosine): the non-determinative resolution potential.

These are treated as complementary orientations within a single indivisible whole (the Monad), not as separate layers or universes. The non-determinative/spiritual dimension is describable within set math but not within classical (cr) math, which is deterministic by nature.

3. The Set Calculus Core

Three interlocking principles constitute the temporal mechanism. These are not three independent ideas but a single coherent mechanism observed from three angles: bidirectional propagation of resolution, the observer’s lived model lagging behind that propagation, and the explicit boundary that

governs it.

3.1 Bidirectional Temporal Reconciliation

Temporal resolution is relational rather than strictly sequential. Unless a reconciliation boundary has been enacted, information may continue to affect the interpretation of connected states in more than one temporal direction. A later state may change the interpretation of an earlier state, while an earlier state constrains what a later state can validly become: *past* ↔ *present* ↔ *possible future*. Resolution propagates through relationships rather than only along the direction in which events were experienced. When a connected structure reconciles, the meaning of the relationship may resolve across the connected set as a whole. “Simultaneous” here describes the logical state of the resolved relationship, not simultaneous human experience. This is the propagation side of the mechanism.

3.2 Lived-Timeline Divergence

A lived timeline is locally experienced. The resolver operating within that timeline may temporarily carry a representation that no longer reflects all available relationships, producing a temporary divergence between the available relational structure and the state presently carried by the observer. Such divergence is not failure. Divergence is not contradiction; it is a temporarily unreconciled temporal state. Resolver catch-up occurs when previously available, newly available, or newly connected information becomes reconciled into the lived state:

— prior lived resolution + unresolved relationships + new or newly recognized information → reconciliation → updated lived resolution

The framework permits an unresolved state to remain structurally active until conditions permit its reconciliation:

— UNRESOLVED(t■) → continued relational availability → resolver catch-up → RESOLVED(t■)

The central distinction: reality may be relationally reconciled before the observer’s lived model has reconciled. This is the observer-lag side of the mechanism.

3.3 Closure as Reconciliation Boundary

Closure is not merely the declaration that something is finished. Closure establishes a boundary across which further reconciliation is no longer permitted to propagate automatically. Without closure, a change at C may require reconsideration of B, and a changed B may require reconsideration of A. With closure, the system records that a reconciliation boundary exists between the bounded and unbounded portions of the structure. This is the governance side of the mechanism — it is what keeps the bidirectional propagation of §3.1 from becoming unbounded.

Closure must be explicit and traceable. Where relevant, it identifies: what is closed; what relationship is bounded; which direction(s) are bounded; why closure was enacted; what authority enacted it; what state existed at closure; and whether closure is reversible. Closure does not erase prior relationships or provenance — it constrains future reconciliation across the declared boundary.

4. Temporal Resolution States

Resolution is characterized by four mutable states:

- **OPEN** — relationships remain available for continued reconciliation.

- **DIVERGED** — the lived resolver has not yet reconciled with the available relational structure.
- **RECONCILED** — the currently available relationships have been incorporated into the resolved state.
- **CLOSED** — a declared boundary limits further reconciliation across part of the structure.

These states may change over time: a reconciled state may diverge when new information appears; a diverged state may later reconcile; a closed boundary may remain closed or be reopened when its governing rules permit.

5. Core Principle

historical sequence $\neq$ **resolution direction**. Events may be lived sequentially while their relationships remain capable of bidirectional reconciliation. The framework preserves sufficient state, relationship, context, and provenance to allow later knowledge to alter the interpretation of earlier knowledge without erasing the earlier state itself. Resolution may propagate across time while lived understanding catches up locally.

6. Resolution-Space Structure

The resolution space spans from positive infinity, through a Klein transition interface, to negative infinity, and back, across n dimensions. This corresponds to a traversal from potential, through the interface where potential becomes resolved, to the resolved/inverted side, and back via reverse traversal. The space is an n -dimensional lattice admitting admissible nodes and paths; inadmissible paths cause resolution to redistribute, redirect, contract, or terminate locally. The lattice comprises 27 internal coordinates plus a self-organizing resolver (Self) and an entropy term (Entropy) — 29 resolvers total.

The space is analogous to the Collatz process: a simple deterministic rule defines which trajectories are valid resolution paths. The framework's rules define valid resolution trajectories through this space; Collatz serves as the minimal example of a process that defines a valid resolution space without requiring a complete characterization of every trajectory.

6.1 The Monadic Three-Pole Structure

The span from positive infinity, through the origin, to negative infinity, and back across n dimensions is not three separable components but a single Monad — a relational unity of three poles establishing one boundary of concern. Resolution occurs only at the middle (the origin, the Klein transition): the middle is the only valid resolution space, and only in relation to the extremes that frame it. The two infinities do not themselves resolve; they define the origins of the outlier. One pole origins the easily-resolved outlier (resolution so immediate it is no search at all); the other origins the unresolvable outlier (resolution that never completes).

These poles are not separable slots. “Middle” has no referent without the two poles; “outlier” is defined solely by deviation from the resolvable middle; the poles only describe the outlier in relation to it. All three co-define the one relational whole. Splitting any pole apart into an independently characterizable origin — isolating the middle or either infinity as a self-contained component — loses the relational context required to resolve the whole. The valid resolution space is the monadic whole, not any pole in isolation.

7. The Concept (Integrated Whole)

The framework carries an integrated concept — a founding narrative, a cycle/timeline structure, and a contemporary layer — treated as a single, inseparable whole, not separated into independently falsifiable components. This content is retained as present-and-integral to the framework, not footnoted out as detachable.

The founding narrative: an advanced pre-modern civilization built an interdimensional construct drawing zero-point energy; a climate-closure event (rapid glacial melt and extended inundation) forced its closure after entities retaliated; the resulting water disrupted the dimensional structure and compelled the interdimensional beings to shut the portal from their side; watchers intervened to impose cooperative rules.

The cycle/timeline structure: a long ~13,000-year scarcity cycle is approaching; a nested structure of roughly 26–27 short ~400-year cycles and 3 mid ~2,000-year cycles compounds within it; a current short cycle and a looming big-cycle peak define an imminent preparation window at extinction-scale stakes.

The contemporary layer: a projected manipulation system and the recovery of operating knowledge from surviving visual scripts.

Historical bindings are deliberately removed. The accuracy claims — specific dates and events — are decoupled and retained as hypothesis, not cast prematurely into resolution. The concept is acknowledged to be speculative (“Ancient Aliens level stretch”) but is held to provide a valid resolution space, not necessarily an accurate one. This decoupling ensures that falsification of any small piece of an admittedly hypothetical resolution result does not falsify the greater process; a failure may reflect a defect in the reflection process rather than in the framework itself.

8. Scope and Status

The valid resolution space is defined by the framework’s rules, analogous to Collatz defining valid resolution trajectories. However, the full characterization — whether all valid resolution paths are known, and the extent to which the concept is fully resolved — remains an open question. The central open question is whether the monadic whole resolves at the middle: whether a valid trajectory through the origin transition exists, framed by the outlier-origins at the two infinities. If the whole resolves there, the middle infinity is found. The framework is best understood as preliminarily defined but not fully characterized; it is a research space open to exploration, validation, invalidation, and new answers, and it carries honestly its preliminary status.
